WordPress Core CVE-2026-119977 Active Exploitation Revalidation - Daily Update

1. Executive Summary

CISA added CVE-2026-119977 to the Known Exploited Vulnerabilities catalog on 3 November 2026. Current Wordfence reporting located in this 7 November daily review says attackers are actively probing the reported upgrade-window RCE condition. Internet-facing WordPress estates therefore remain an immediate exposure-validation priority, not simply a routine patching item. NVD enrichment remains incomplete.

The operative risk is an exposed site that remains on an affected branch, has an incomplete update workflow, or has evidence of unexpected PHP execution or file placement around upgrade activity. The public evidence supports prioritizing remediation and compromise assessment; it does not establish universal compromise or attribute activity to a named actor.

2. Vulnerability Metadata

Field	Value
CVE	CVE-2026-119977
Product / Component	WordPress Core
Weakness	Reported time-of-check/time-of-use race condition during upgrade handling
Severity	Treat as critical operational priority; NVD enrichment pending
Affected Versions	Supporting CVE reporting: 4.7.0 through 7.1.3; validate against current vendor release notes
Fixed Version	Supporting reporting identifies WordPress 7.1.4 and branch backports
Exploitation Status	CISA KEV; active exploitation evidence cited by CISA
Disclosure / KEV Date	2026-11-03 KEV addition

3. Source Review & Confidence

Source	Contribution	Confidence
CISA KEV alert	Active-exploitation prioritization	High
NVD	CVE tracking; enrichment status	High
Wordfence	Release and technical supporting context	Medium
BleepingComputer	Supporting exploitation reporting	Medium

CISA is authoritative for the prioritization decision. NVD is explicitly undergoing enrichment, and this report avoids assigning a final CVSS or relying on secondary sources for definitive affected-build scope.

4. Vulnerability Details

The reported condition concerns an upgrade-time race rather than normal authenticated content administration. That distinction matters: patch validation must include operational controls around update execution, filesystem write locations,

web-server identity, and post-update integrity. A patch inventory alone cannot establish whether an upgrade was interrupted or abused before remediation.

5. Attack Scenarios

1. An internet-facing WordPress site enters an upgrade path while an attacker races file or code placement into an upgrade-related location.
2. A managed hosting fleet rolls out updates with broad filesystem permissions; one weak tenant becomes a foothold for persistence or credential collection.
3. A site is patched after exploitation evidence; retained web shells, unfamiliar administrator accounts, cron jobs, or modified themes/plugins preserve access.

6. Threat Landscape & Exploitation Status

CISA KEV inclusion is sufficient to elevate this issue into an urgent remediation queue. No actor, campaign, or victimology claim is made in this report. Teams should preserve web, WAF, authentication, deployment, and filesystem telemetry before cleaning suspected persistence.

7. Affected Products and Exposure

Exposure Pattern	Why It Matters	Action
Public WordPress origin	Externally reachable upgrade workflow	Patch and investigate first
Managed/multi-tenant hosting	Shared automation and write permissions increase blast radius	Review deployment identity and tenant isolation
Internal editorial service	Lower reachability, but privileged content/admin data	Patch and validate access controls
Fully patched, integrity-checked host	Reduced but not eliminated risk	Hunt historical upgrade-window activity

8. Mitigation and Workarounds

Priority	Owner	Action
Critical	Web platform owner	Inventory all WordPress versions and update to the vendor-supported fixed release/backport.
Critical	SOC / IR	Preserve and review web/PHP, WAF, authentication, deployment, and filesystem data around upgrades.
High	Hosting engineering	Restrict write permissions; separate deployment identity from runtime web identity.
High	Application owner	Rotate exposed WordPress/admin and deployment credentials if suspicious execution is confirmed.

9. Detection Engineering

Signal	Telemetry Source	Analytic Goal
PHP created below upgrade or uploads	EDR/FIM/web host logs	Identify likely web-shell placement

paths		
Web server spawning shell/interpreter	EDR process telemetry	Identify post-exploitation execution
New privileged WordPress user near upgrade event	Application audit logs	Identify persistence

```
title: WordPress Web Process Spawning Shell or Script Interpreter
status: experimental
logsource:
  product: linux
  category: process_creation
detection:
  web_parent:
    ParentImage|endswith:
      - '/apache2'
      - '/httpd'
      - '/php-fpm'
  child:
    Image|endswith:
      - '/sh'
      - '/bash'
      - '/python'
      - '/perl'
  condition: web_parent and child
level: high
```

```
DeviceProcessEvents
| where Timestamp > ago(30d)
| where InitiatingProcessFileName in~ ('apache2','httpd','php-fpm')
| where FileName in~ ('sh','bash','python','perl','curl','wget')
| project Timestamp, DeviceName, FileName, ProcessCommandLine, InitiatingProcessCommandLine
```

10. Threat Hunting

Hypothesis: an attempted exploit or post-exploitation action left unexpected PHP, archive, or shell activity in WordPress upgrade/content locations.

```
DeviceFileEvents
| where Timestamp > ago(30d)
| where FolderPath has_any ('/wp-content/upgrade','/wp-content/uploads','/wp-admin')
| where FileName endswith '.php' or FileName endswith '.phtml'
| project Timestamp, DeviceName, FolderPath, FileName, InitiatingProcessFileName
| order by Timestamp desc
```

Triage hits against approved deployment manifests and correlate with upgrade timestamps, HTTP requests, and administrator-login events.

11. MITRE ATT&CK Mapping

Technique	Name	Evidence / Rationale
T1190	Exploit Public-Facing Application	Relevant exposure path for an internet-facing CMS; not a claim of confirmed compromise.
T1505.003	Web Shell	Hunt mapping for unexpected server-side script persistence.
T1059	Command and Scripting Interpreter	Hunt mapping for web-process child shell activity.

12. Validation / Lab Testing

No exploit was executed and no production validation was performed. Queries are detection hypotheses and require environment-specific field normalization and tuning.

13. Recommended Actions Summary

Priority	Owner	Action
Critical	Vulnerability management	Close exposure inventory and patch gaps today.
Critical	SOC	Hunt upgrade-adjacent file/process activity before and after patching.
High	Platform engineering	Validate least privilege and immutable/declarative deployment controls.
